Turnover in the stock and forex markets

1 Ratio of the total value of share trading and the market capitalisation of domestic companies, in US dollar terms for 2006, 12-month annualised monthly velocity computed in February 2006; in per cent.  
2 Daily spx transactions, in billions of US dollars.  
3 NYSE and Nasdaq.

Sources: EBS; World Federation of Exchanges data.
appreciating trends. These trends also induced an increase in hedging activity, which further supported trading volumes. Second, interest differentials encouraged so-called “carry trading”, ie investments in high interest rate currencies financed by short positions in low interest rate currencies, if the target currencies, like the Australian dollar, tended to appreciate against the funding currencies, like the US dollar. Such strategies fed back into prices and supported the persistence of trends in exchange rates. In addition, in the

II/Alternative views on the stability of the international financial system

A/ Everything is under control?

B/ Dancing on a volcano!
A/ Everything is under control?

- The « new Bretton Woods » hypothesis

- The market operators are very confident …
The « new Bretton Woods » hypothesis

- The current international monetary & financial system works like the B-W system

- The international system is composed of:
  - a core (the US & the eurozone) issuing the international currencies
  - and a periphery with export-led growth in emerging economies based on undervalued currencies

This new B-W system stability hypothesis is based on the alleged complementary situations of core/periphery countries
Market operators are very confident

• The spreads on yields between the US and the emerging markets have declined to historical low levels
• The volatility of exchange rates and interest rates exhibits a downward trend

Profitability

In all economies considered, ROE declined after 2000, reached a trough in 2002, and then recorded a rapid recovery in all areas, in a range of 8 to 12 percentage points (Graph 4.3, right-hand panel).

Graph 4.3

Financial leverage and return on equity of listed companies

1 Ratio of financial debt and equity, calculated at book value; sample of non-financial companies that represent approximately 90% of the market capitalisation of their respective markets. Observations with negative equity are excluded. 
2 Return on equity is the ratio of net profits to end-of-year equity, calculated at book value. Observations with negative equity are excluded.

Sources: Thomson Financial; Worldscope.

Since ROE is a backward-looking indicator, whereas asset price volatility may be closely tied to expected profitability, Graph 4.4 reports the expected earnings per share over the last decade for the major industrial regions. The data show that expected profitability has increased very rapidly since the beginning of 2004 and that it now stands at its highest level in the period considered.

Graph 4.4

Expected earnings per share of listed companies

1 January 1986 = 100 (for the euro area, December 1999 = 100); Two-years-ahead expected net income for the companies included in the S&P 500 for the United States and the respective MSCI indices for the other countries.

B/ Dancing on a volcano!

- The « new Bretton Woods » view is fallacious: the international growth regime is not sustainable for economic & social and ecological reasons
- Existing BoP imbalances are not sustainable
- LDC debt and financing is not sustainable
- Large exchange rate misalignments
- Huge accumulation of reserves & excess liquidity in the world economy
- Excessive risk taking from short-sighted investors
# The « new Bretton Woods » fallacy

|--------------------------|--------------------------------------------------|
| Fixed & adjustable exchange rate system | Large currencies are floating  
Pegged regimes for LDC |
| Small BoP imbalances  
US BoP surplus | Large BoP imbalances  
Huge US deficit  
LDC financing DC |
| Capital controls  
=> Small size & relative stability of capital flows | Financial deregulation  
Washington Consensus  
=> Increasing & destabilizing role of capital flows |
| Dollar monopoly  
Hegemonic stability | Increasing role of the euro  
Currency competition  
=> exchange rate instability |

Figure 1.9 Net private debt flows to developing countries, 1990–2004

$ billions

Net bond flows

Net bank lending

Increased risk-taking from short-sighted investors

• Due to excessive confidence, investors are increasing their risk positions, as they did on the eve of the 1997 – 98 Asian crisis

• This is shown by the fast growth of derivative markets due to speculation
Equity and credit market-based risk tolerance indicators

Indicator of risk tolerance: equity markets\(^1\)

Concluding remarks

• The international monetary & financial system certainly is not under control, but rather exhibits large imbalances and important potential sources of instability
• This system leads to growing inequality among & within countries
• Investors confidence is high now as it was just before the Asian crisis

• There is an urgent need for radical reforms (IMF) and the introduction of strong public regulations (capital controls to start with)
• Existing regulatory systems are insufficient and have perverse effects (Basle II)
• In fact, financial reforms would not be enough: there is a need for an alternative model of globalization giving a high priority to the supply of global public goods: health, education, water and financial stability
